The Missing Mass

Dynamics of galaxy clusters

- X-rays from gas in clusters
- Dynamics of galaxy clusters
- Rotational speed of galaxies
- Gravitational lensing

Large Scale Rotation

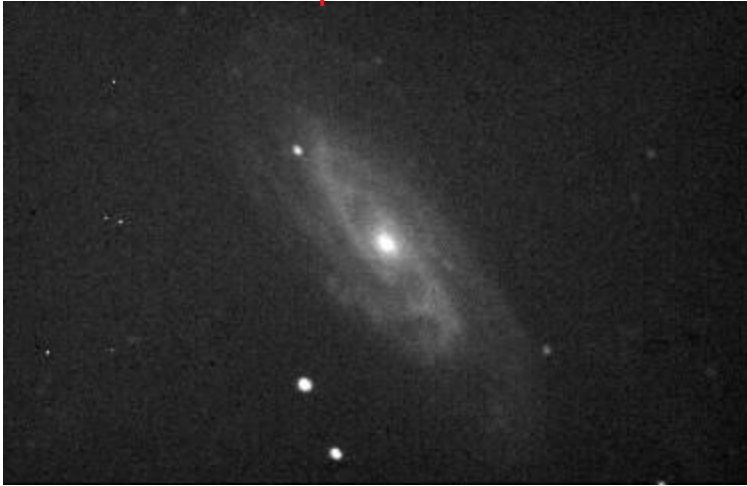

Doppler shift measurements at 21cm indicate that spiral galaxies rotate.

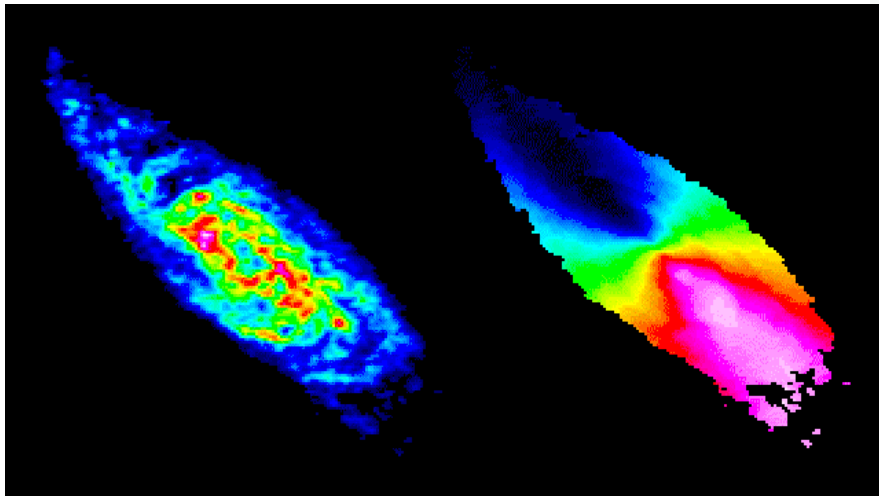

NGC 3198

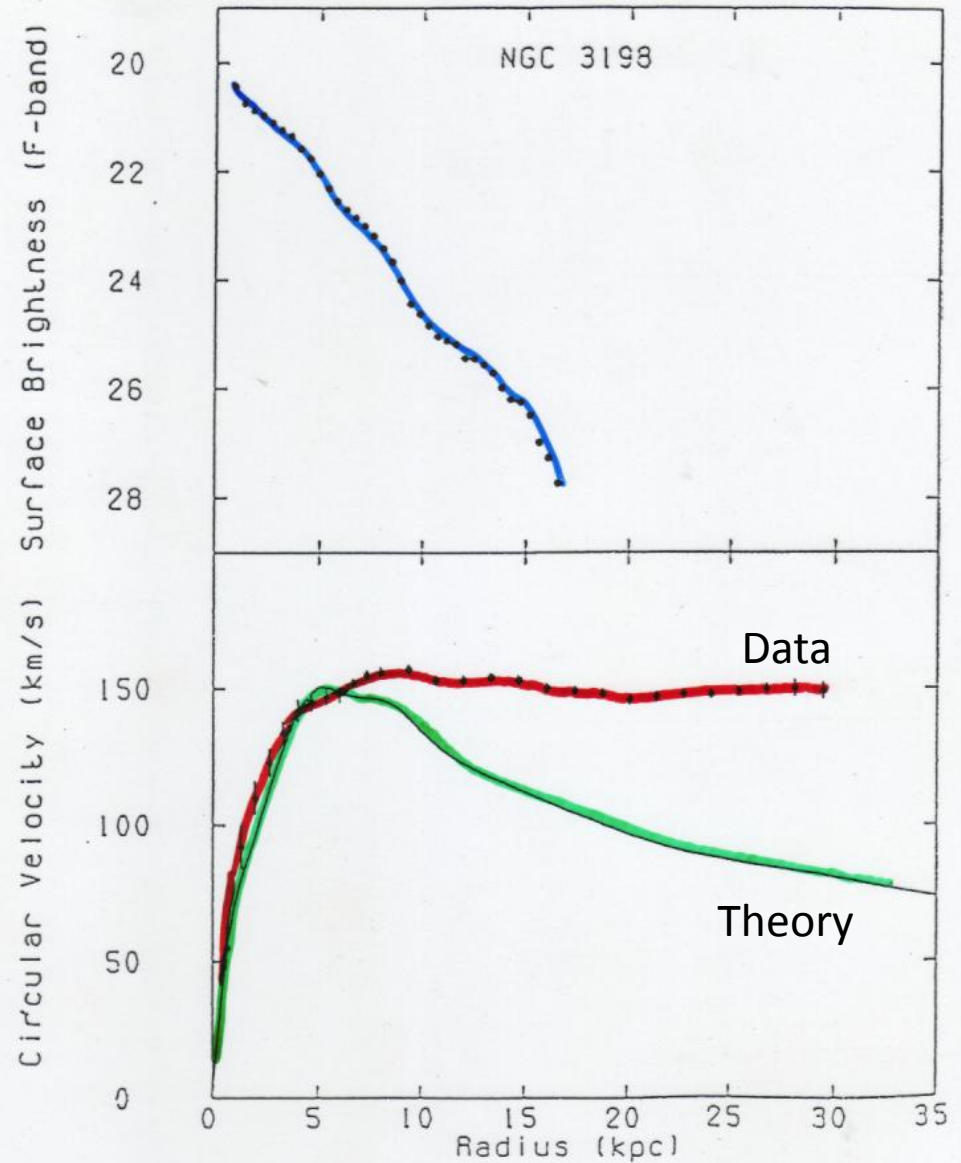

Optical

21 cm

Rotation Curve
Measurements

Dark Matter Candidates

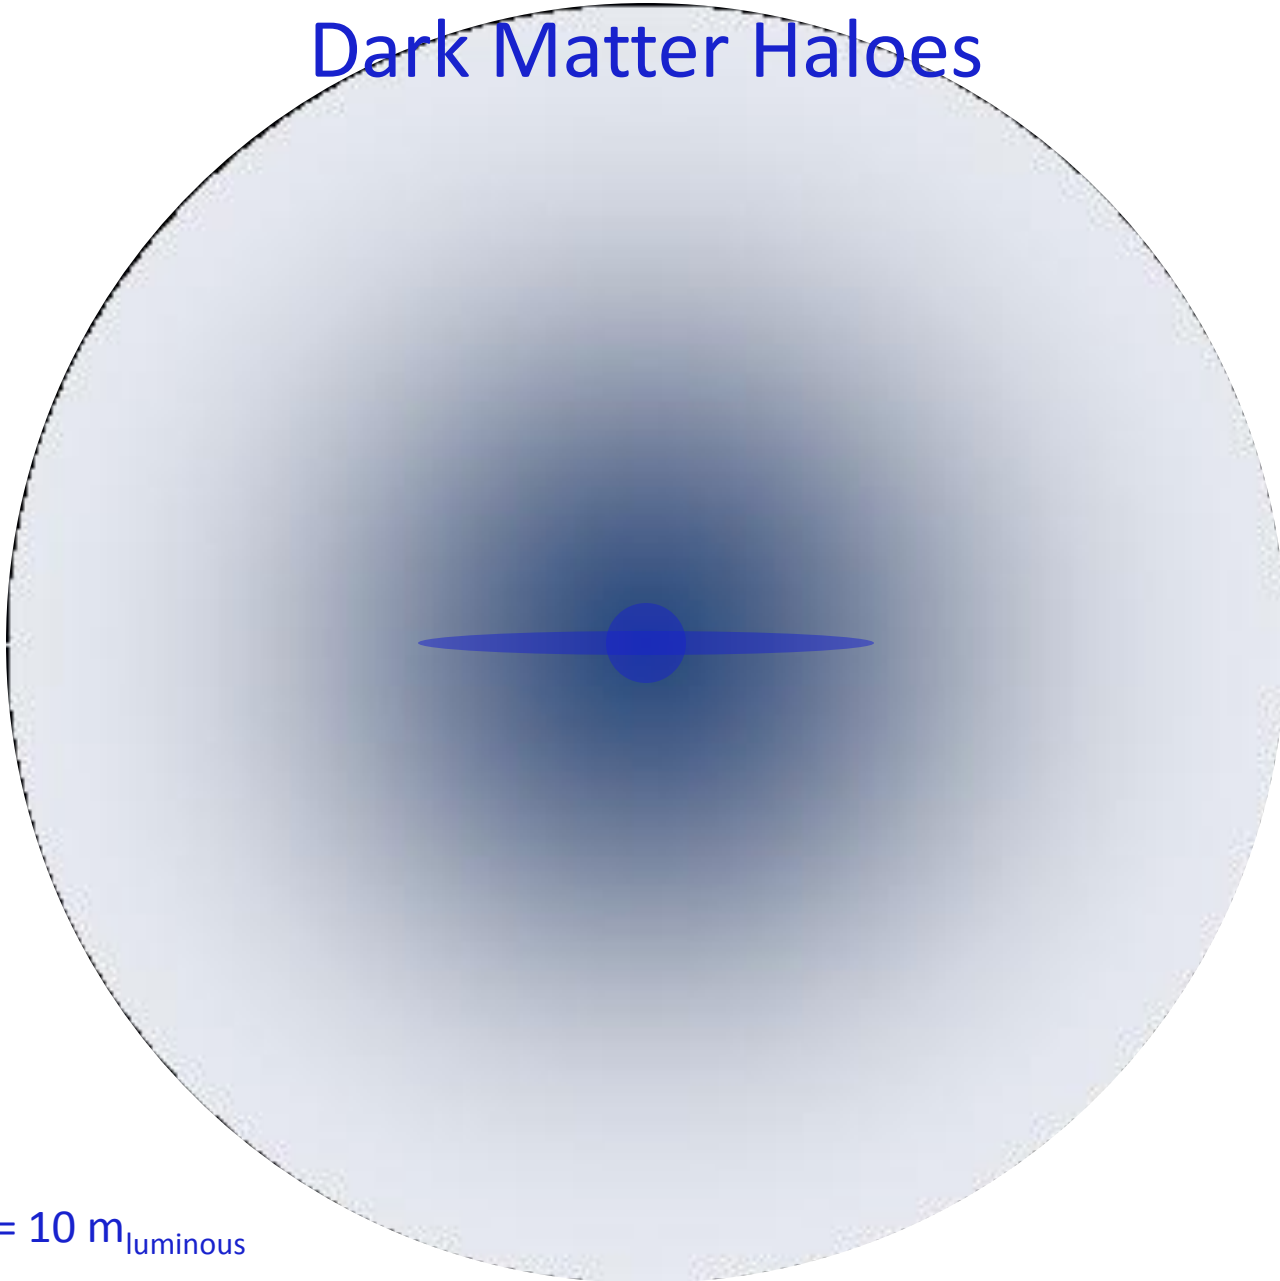

Axions

- $10^{-11} m_e < m < 10^{-9} m_e$
- Solves strong CP problem from particle physics

WIMPS

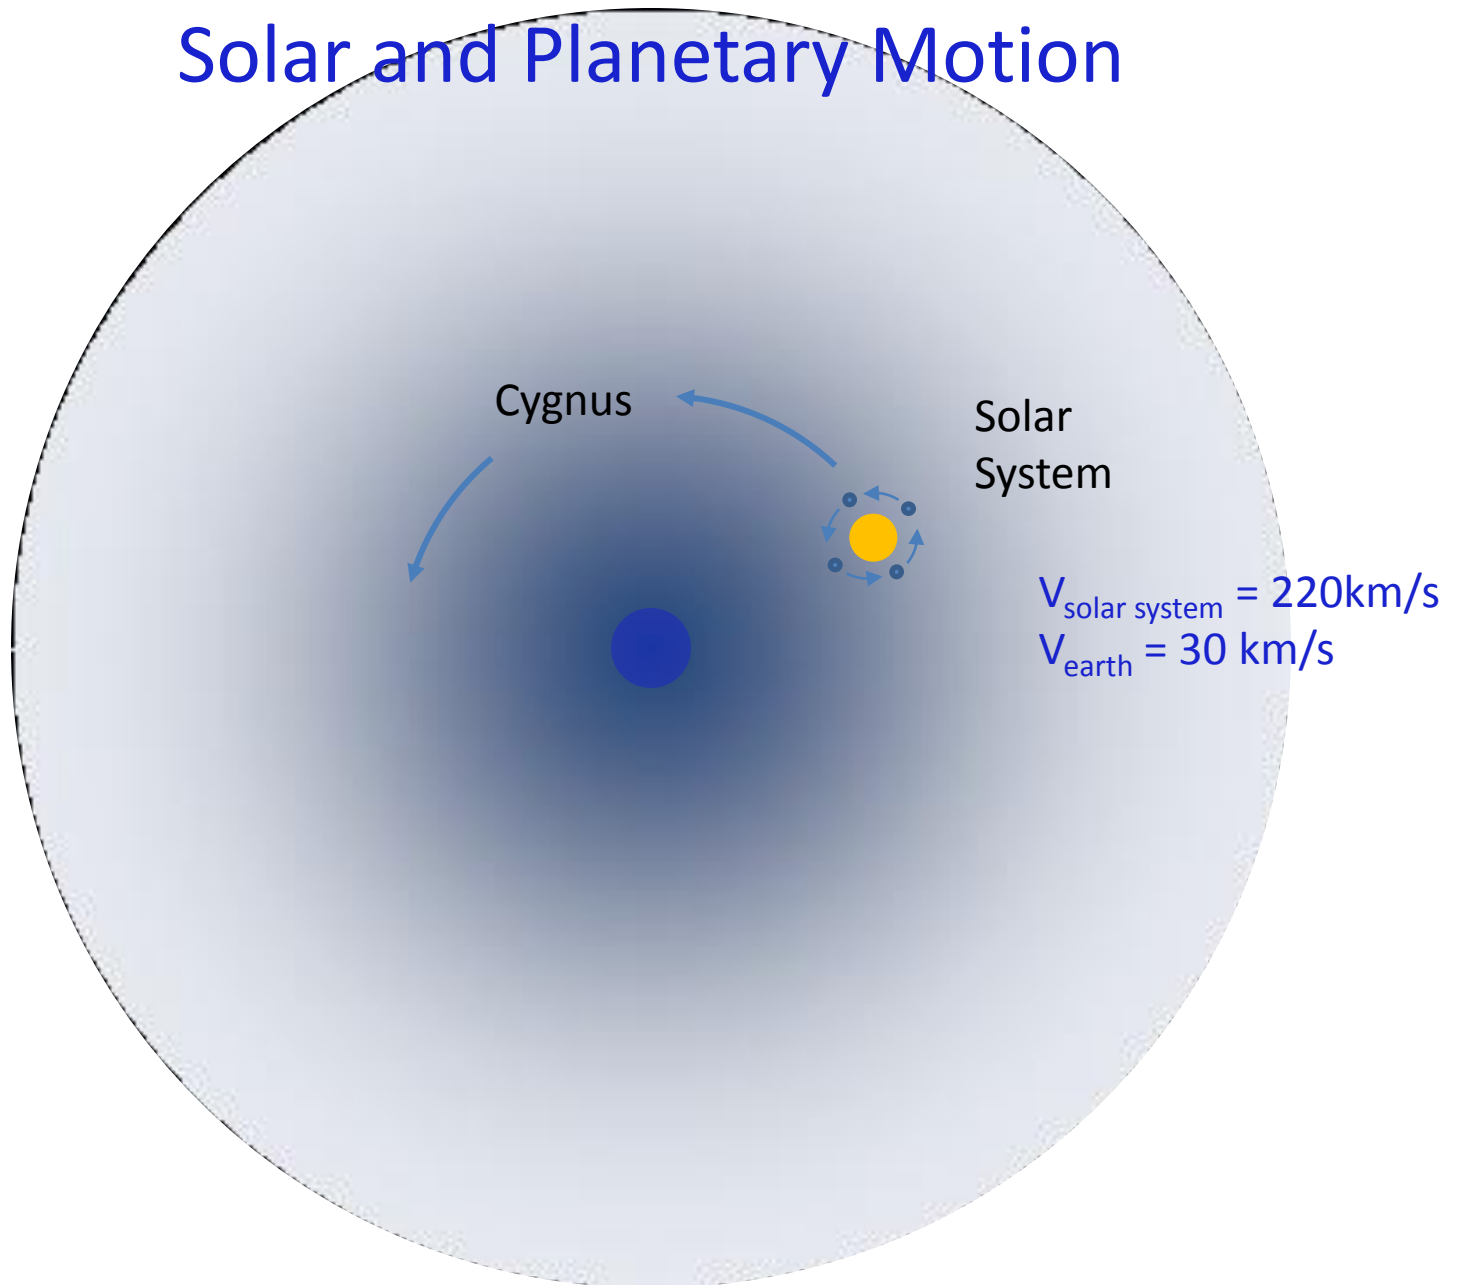

- Weakly Interacting Massive Particles (WIMPs)
 $10 m_p < m < 10^4 m_p$
- Weak interaction predicted for relic particles from the big bang.
- WIMPs are also motivated by supersymmetry.

Dark Matter Haloes

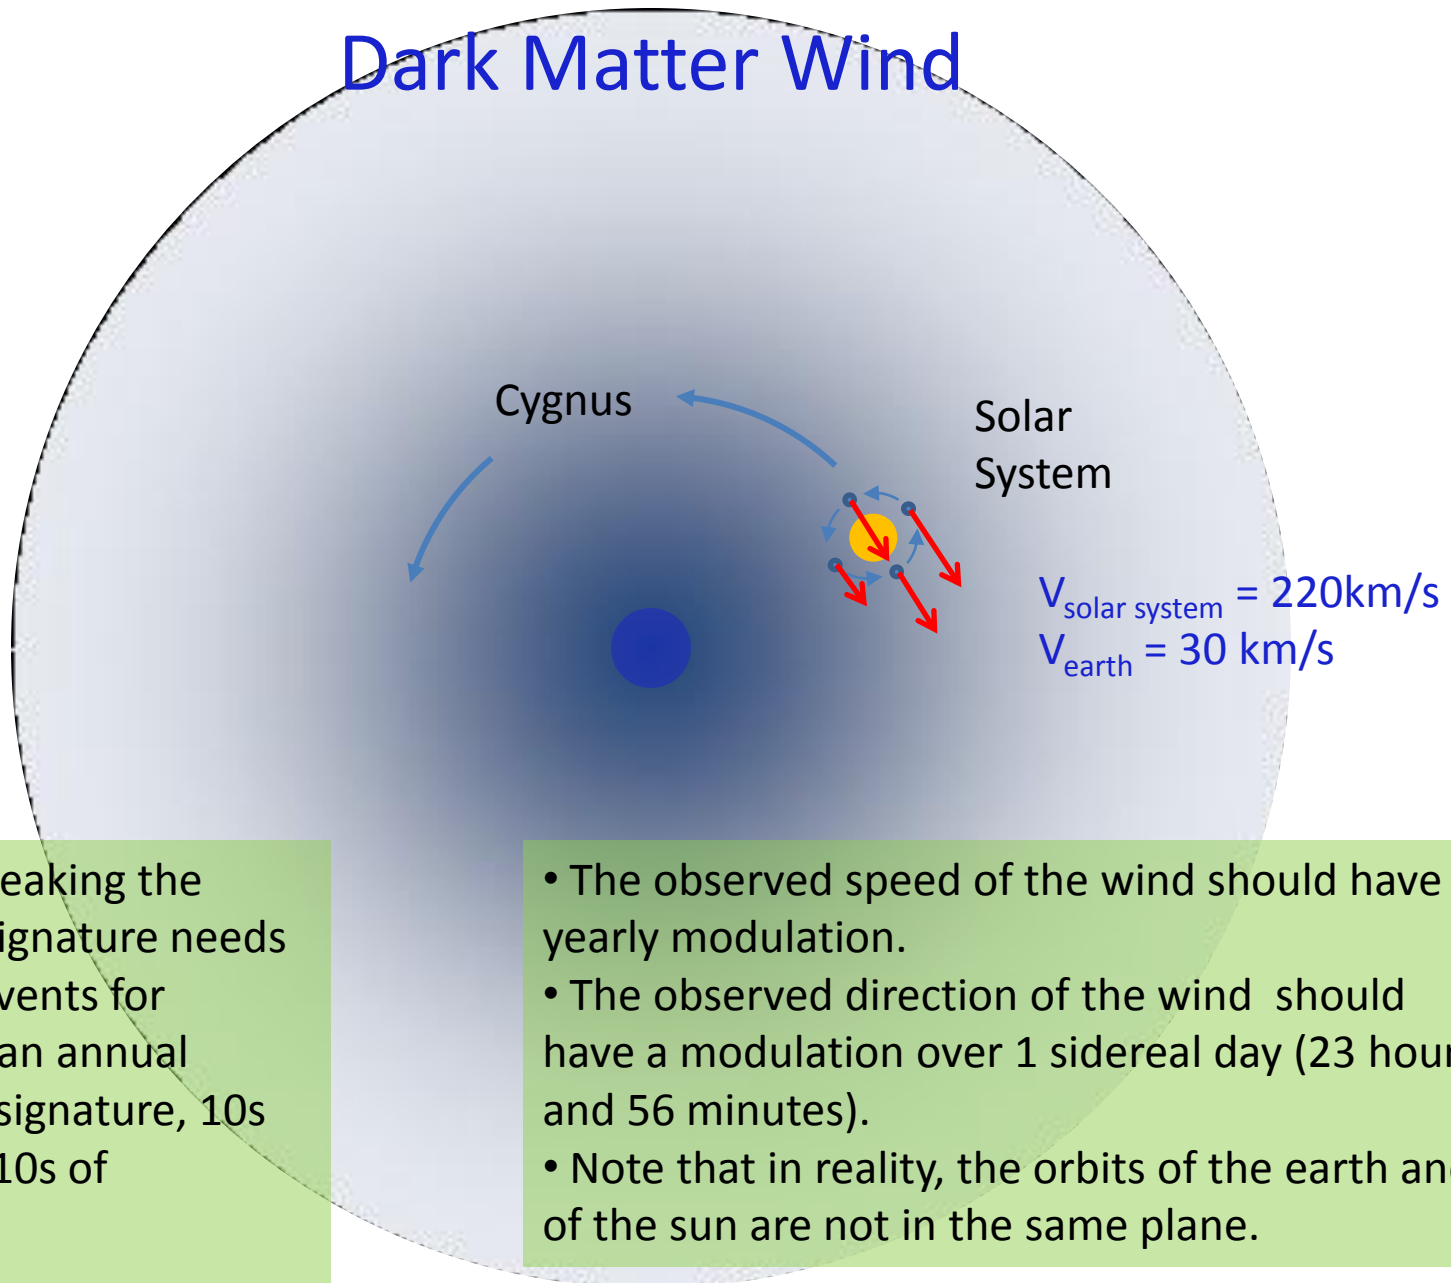

$$m_{\text{dark matter}} = 10 m_{\text{luminous}}$$

Solar and Planetary Motion

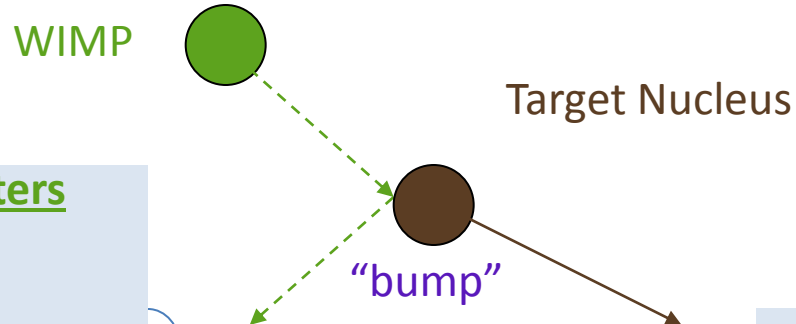

Dark Matter Wind

Generally speaking the directional signature needs 1000x less events for detection than annual modulation signature, 10s rather than 10s of thousands.

- The observed speed of the wind should have a yearly modulation.
- The observed direction of the wind should have a modulation over 1 sidereal day (23 hours and 56 minutes).
- Note that in reality, the orbits of the earth and of the sun are not in the same plane.

Direct Detection of WIMPs

WIMP parameters

Mass

10GeV – 10TeV

Mass Density

.3GeV/cm³

Velocity

220 km/sec

Cross-section

Spin Independent:

$\sigma_{SI} < 10^{-44} \text{ cm}^2$

Spin Dependent

$\sigma_{SD} < 10^{-38} \text{ cm}^2$

Flux = $10^3 - 10^6$
WIMPS/cm²/s

Detector parameters

Recoil Energy

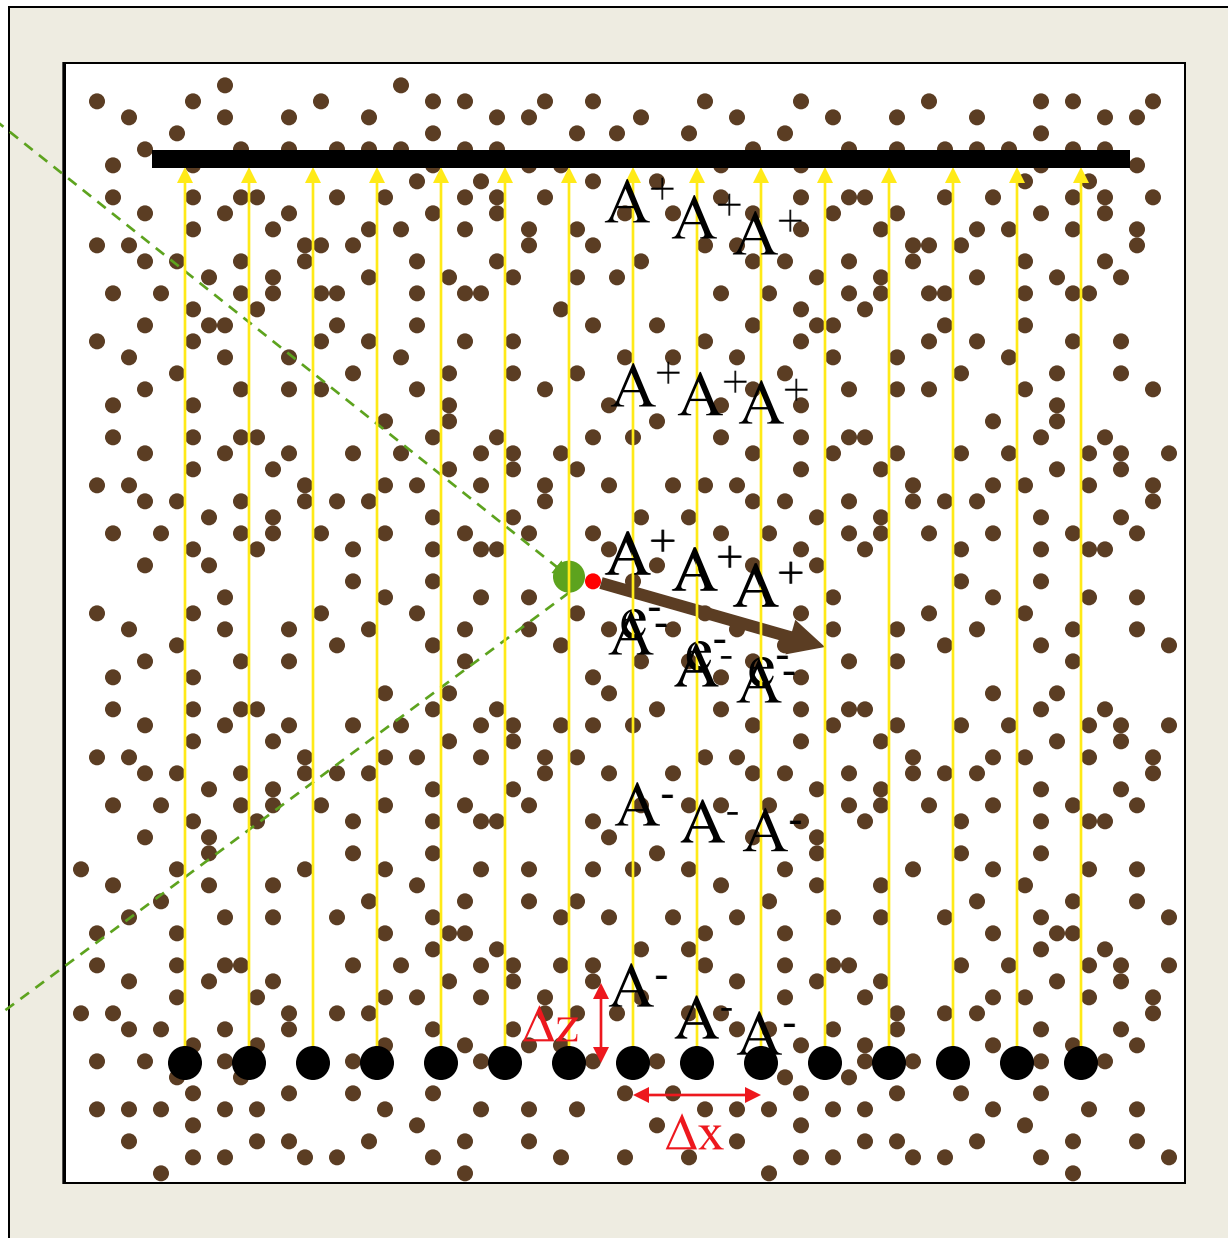

~keV/amu

Event rate

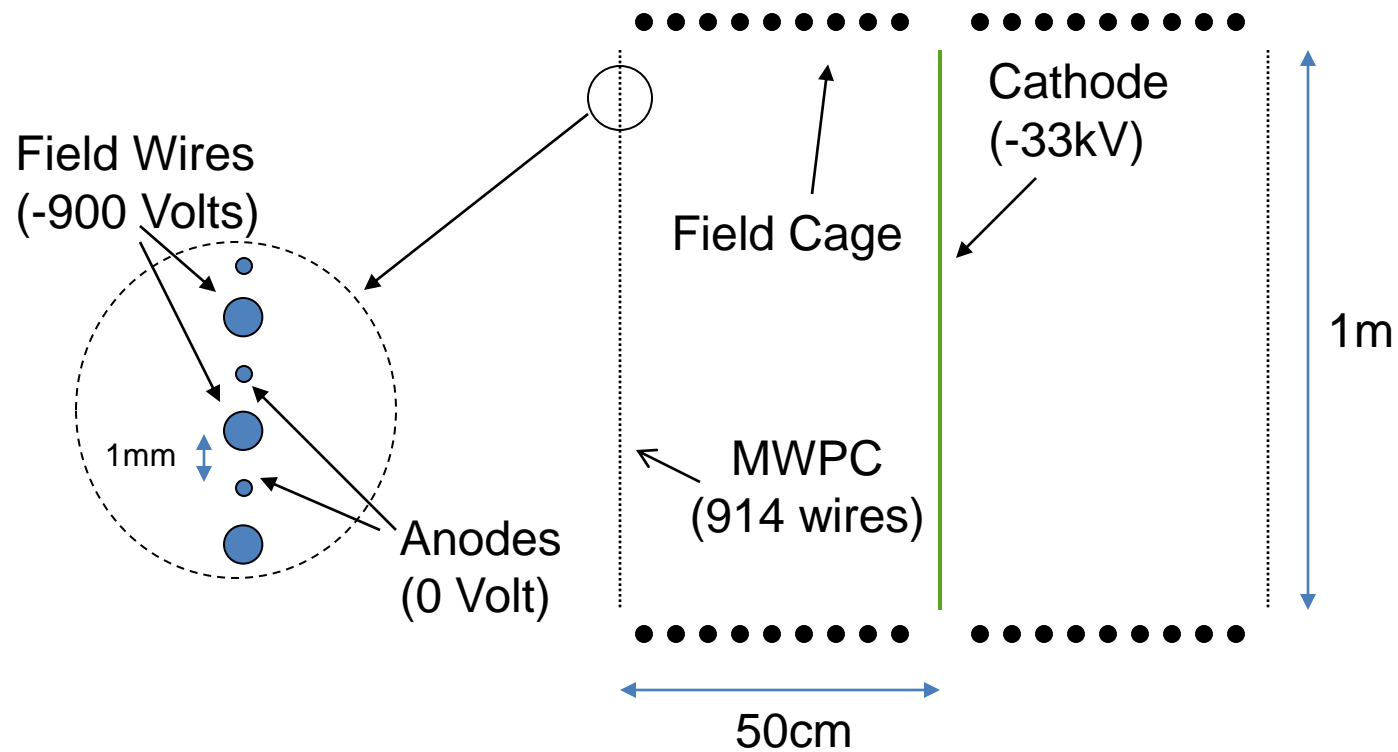

1 / kg / day *

$(\sigma/10^{-35} \text{ cm}^2) * (100 \text{ GeV/m})$

The DRIFT Concept

The Drift-Ile detector

Low Diffusion in CS2

$$\sigma = \sqrt{\frac{2kTL}{eE}}$$

DRIFT Operating Parameters

$$E_{\text{drift}} = 600 \text{ V/cm}$$

$$T = 300 \text{ K}$$

$$L = 50 \text{ cm}$$

$$v_{\text{drift}} = 60 \text{ m/s}$$

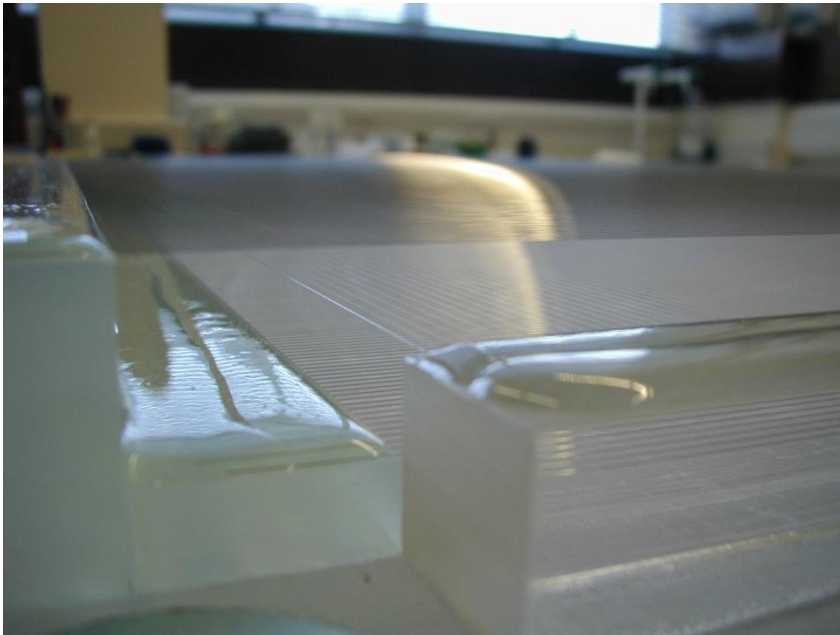

$$t_{\text{drift}} = 0 - 8.33 \text{ ms}$$

$$\sigma_{\text{diffusion}} = .65 \text{ mm}$$

$$\sigma_t = 0 - 10 \text{ } \mu\text{s}$$

DRIFT – Directional Recoil Identification From Tracks

Started = 1998, US/UK
Underground in Boulby, England in 2001
Current operating detector = **DRIFT-II**d
Technology = Negative ion TPC with
MWPC wire readout

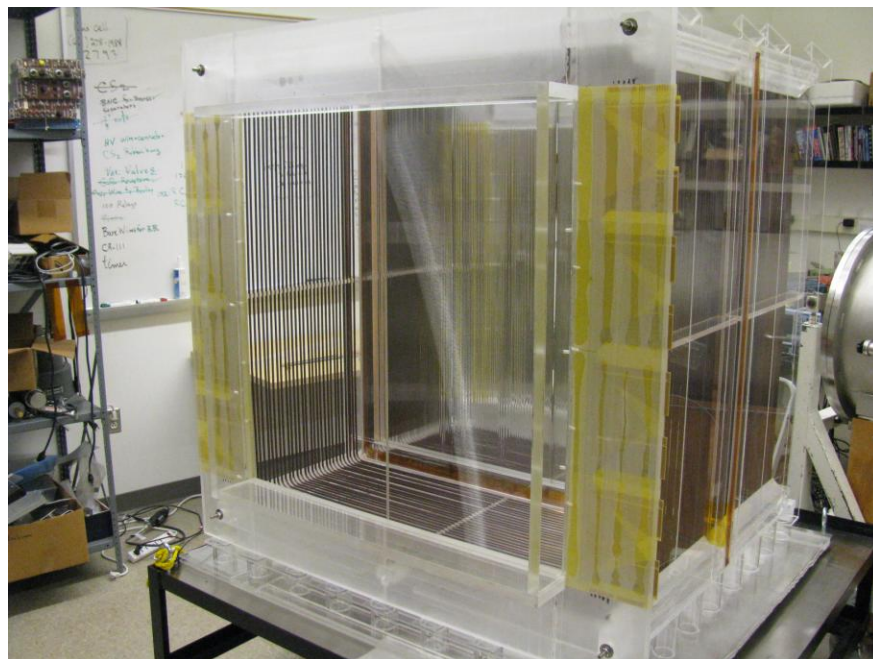

xyz resolution = 2 mm, $\sim < 2$ mm, 0.2 mm,
no absolute
Target = 30 Torr CS_2 + 10 Torr CF_4
Fiducial volume = 800 liters
F mass = 33.3 g
Limit setting threshold = 50 keVr

New MWPC

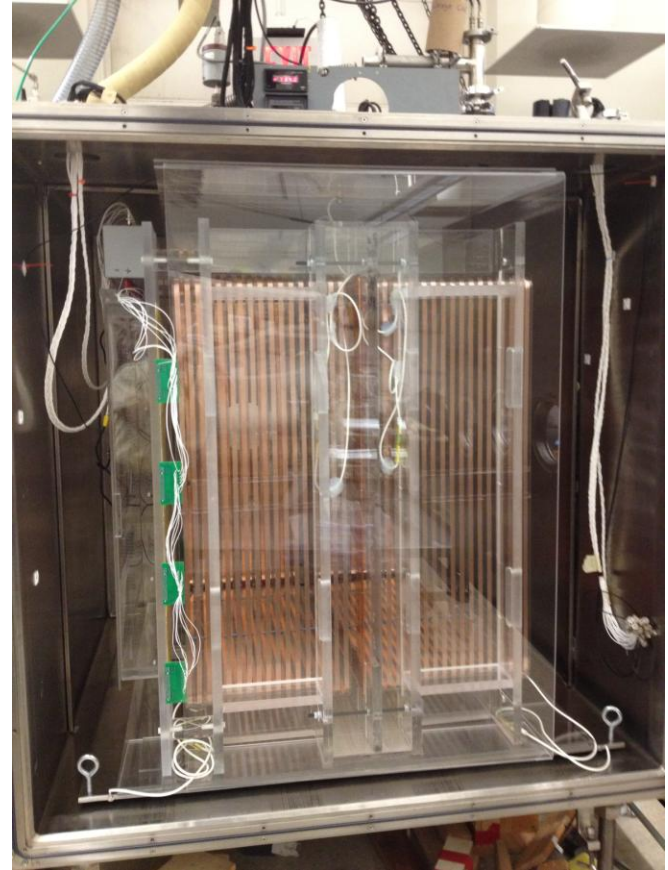

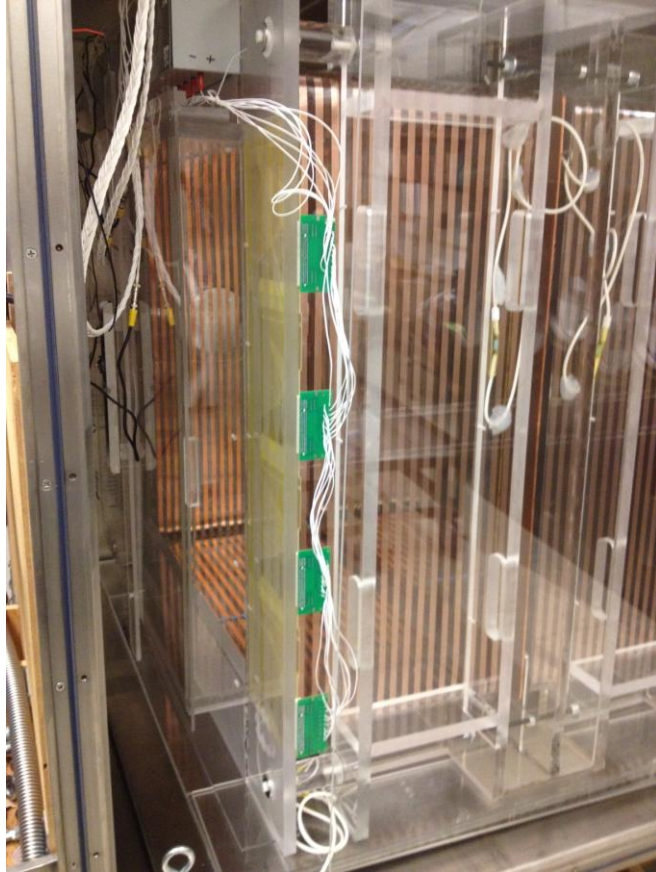

Testing the new MWPC at Oxy

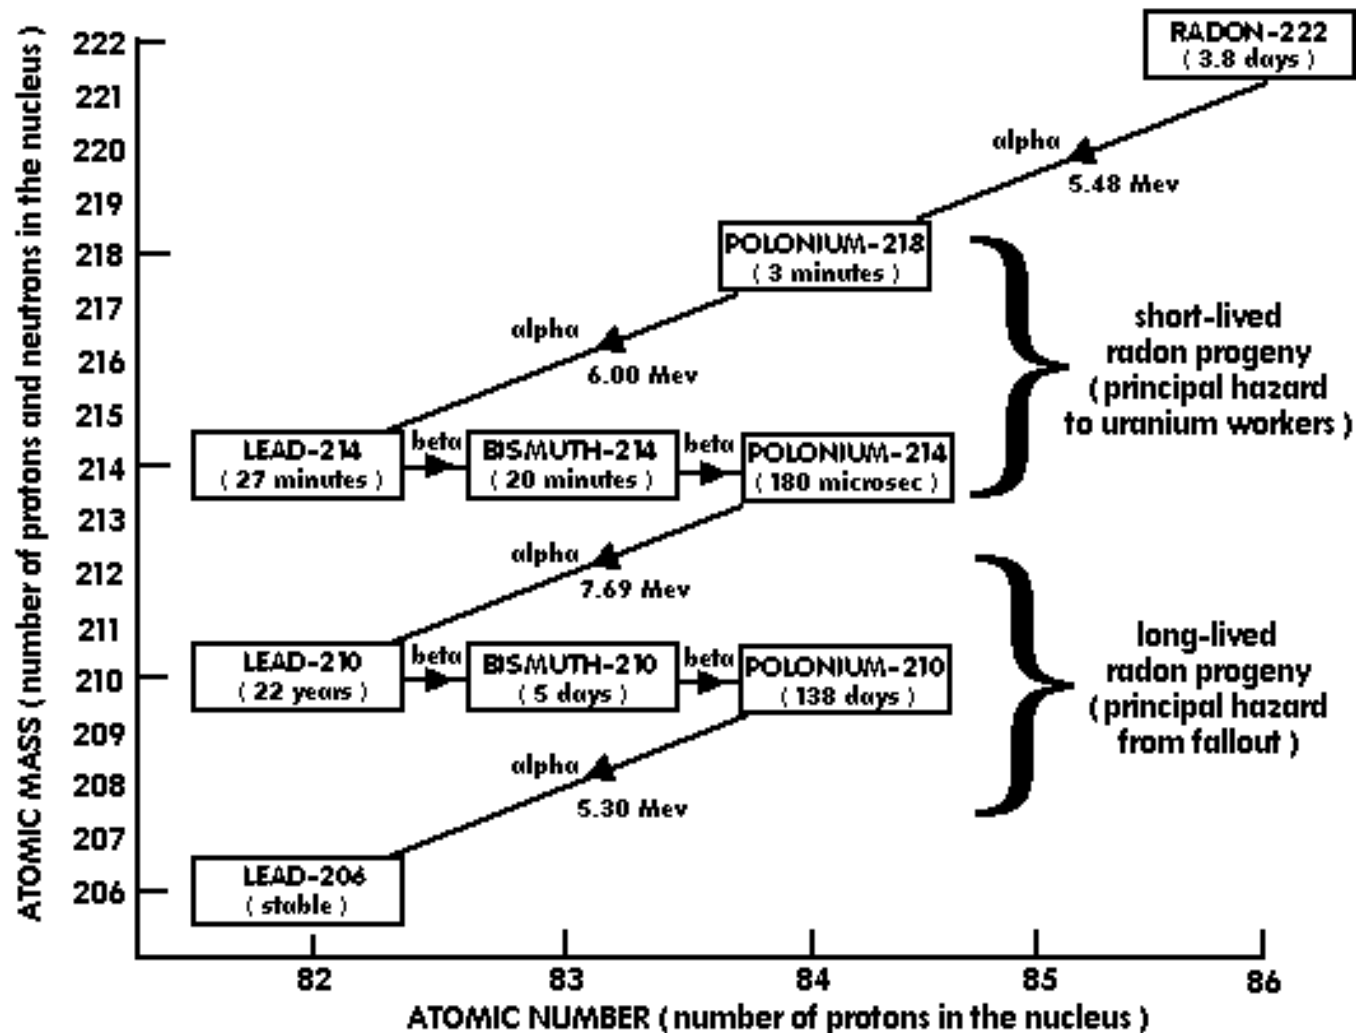

New MWPC on Field Cage

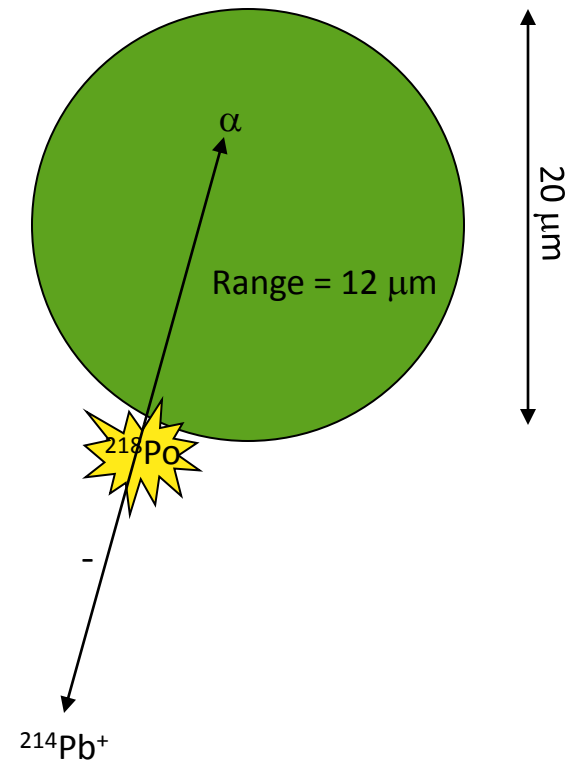

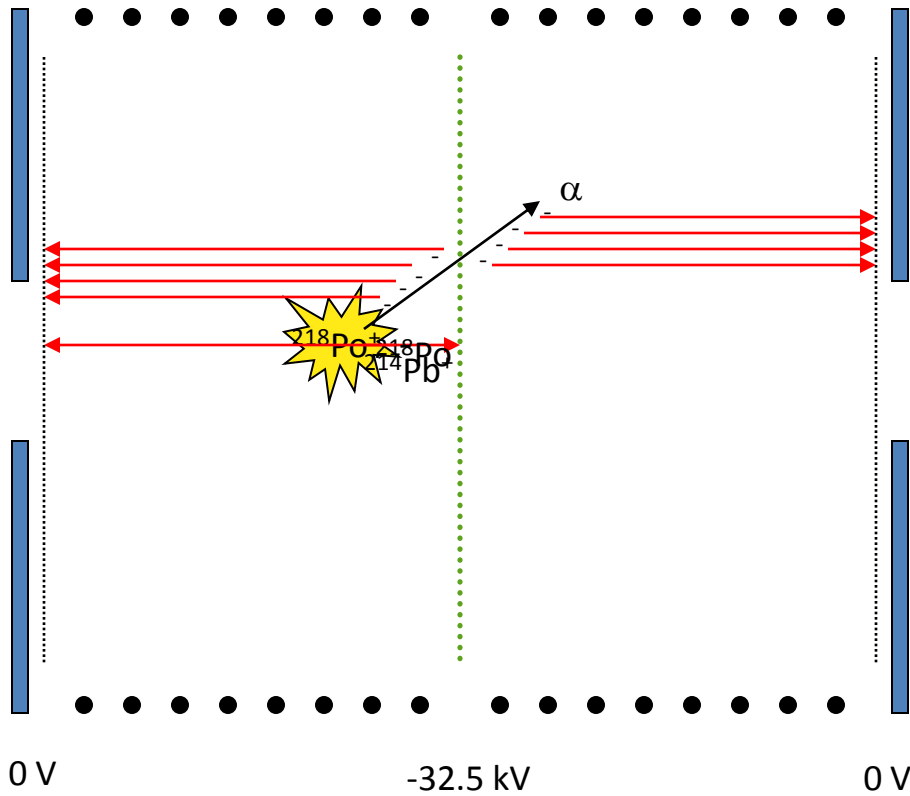

Detector with New MWPC ready for Testing

Radon Progeny

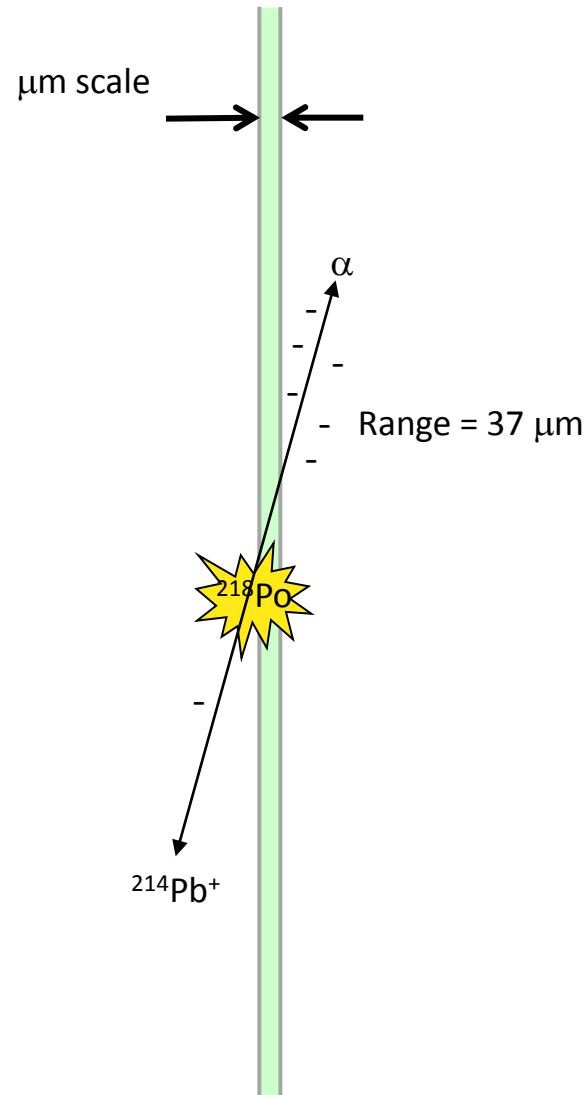

Radon Progeny Recoils (RPR)

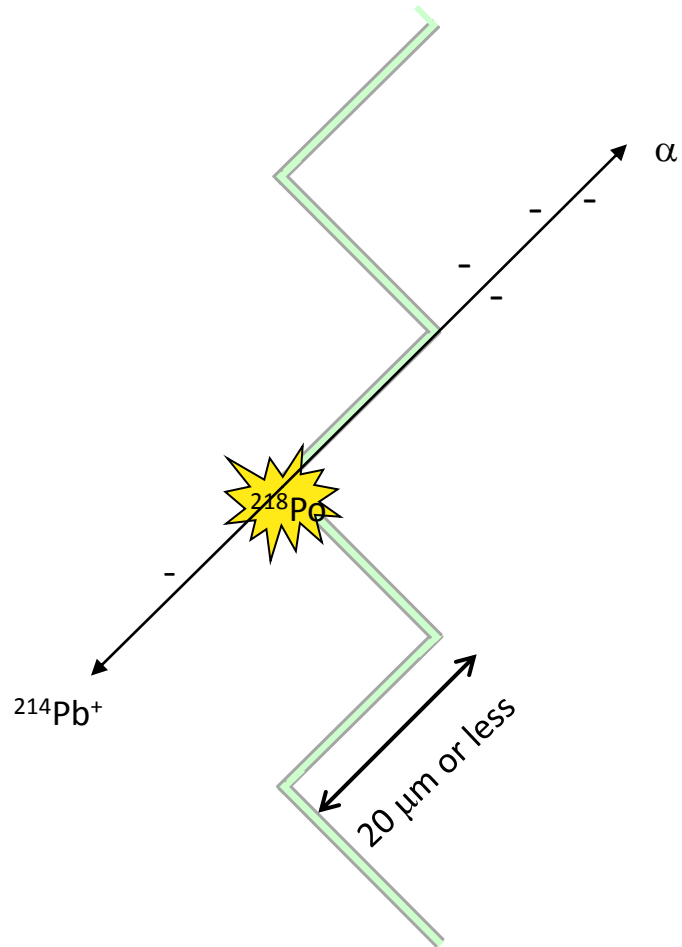

The solution – Part I

Give the alphas few places to hide in an aluminized Mylar thin film.

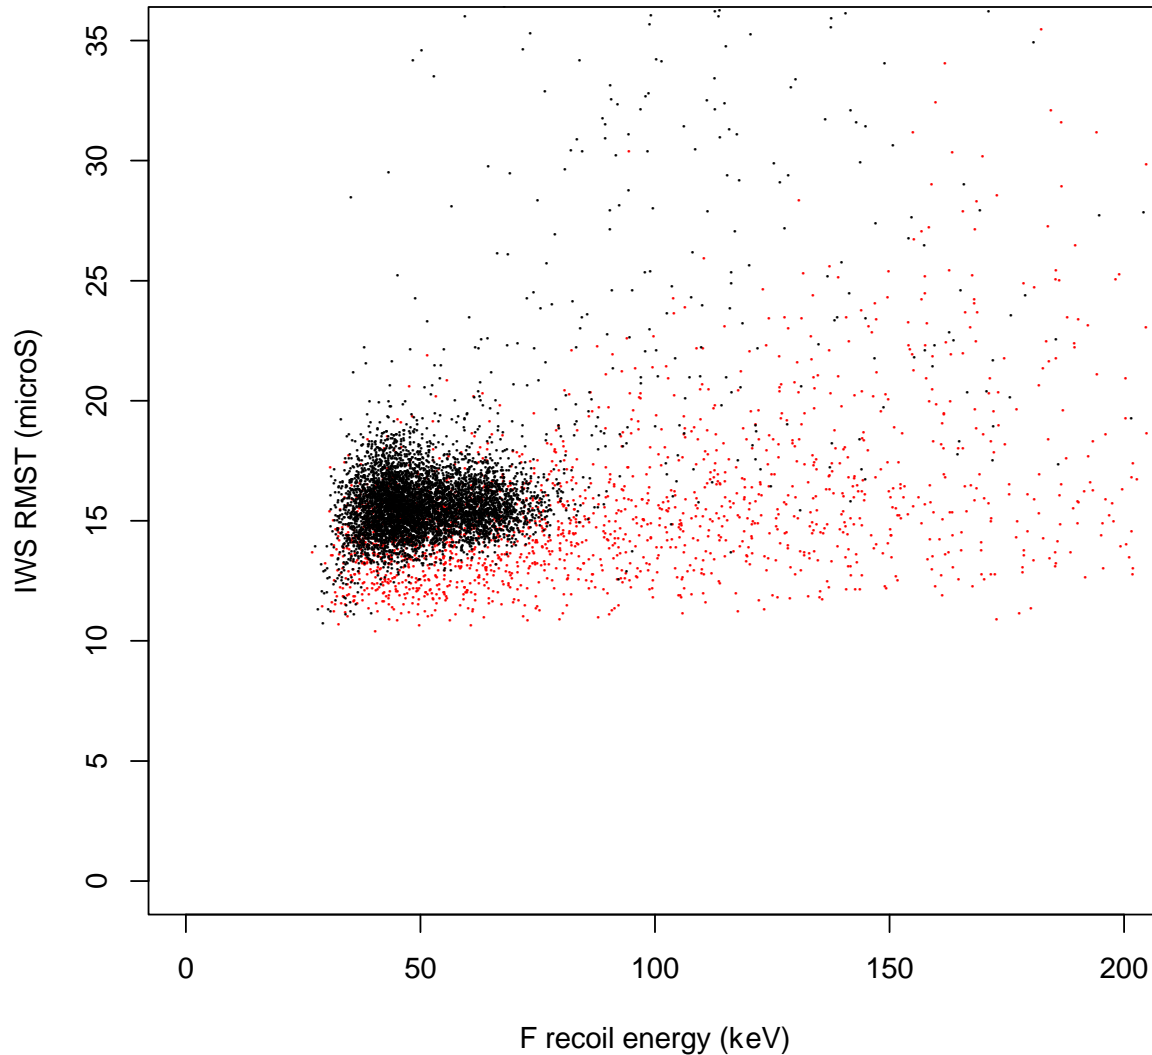

The solution – Part II

Give the alphas **no** place to hide in a **texturized** aluminized Mylar thin film.

DRIFT-IId Data

All Background–Neutron Runs
F equivalent energy vs Width

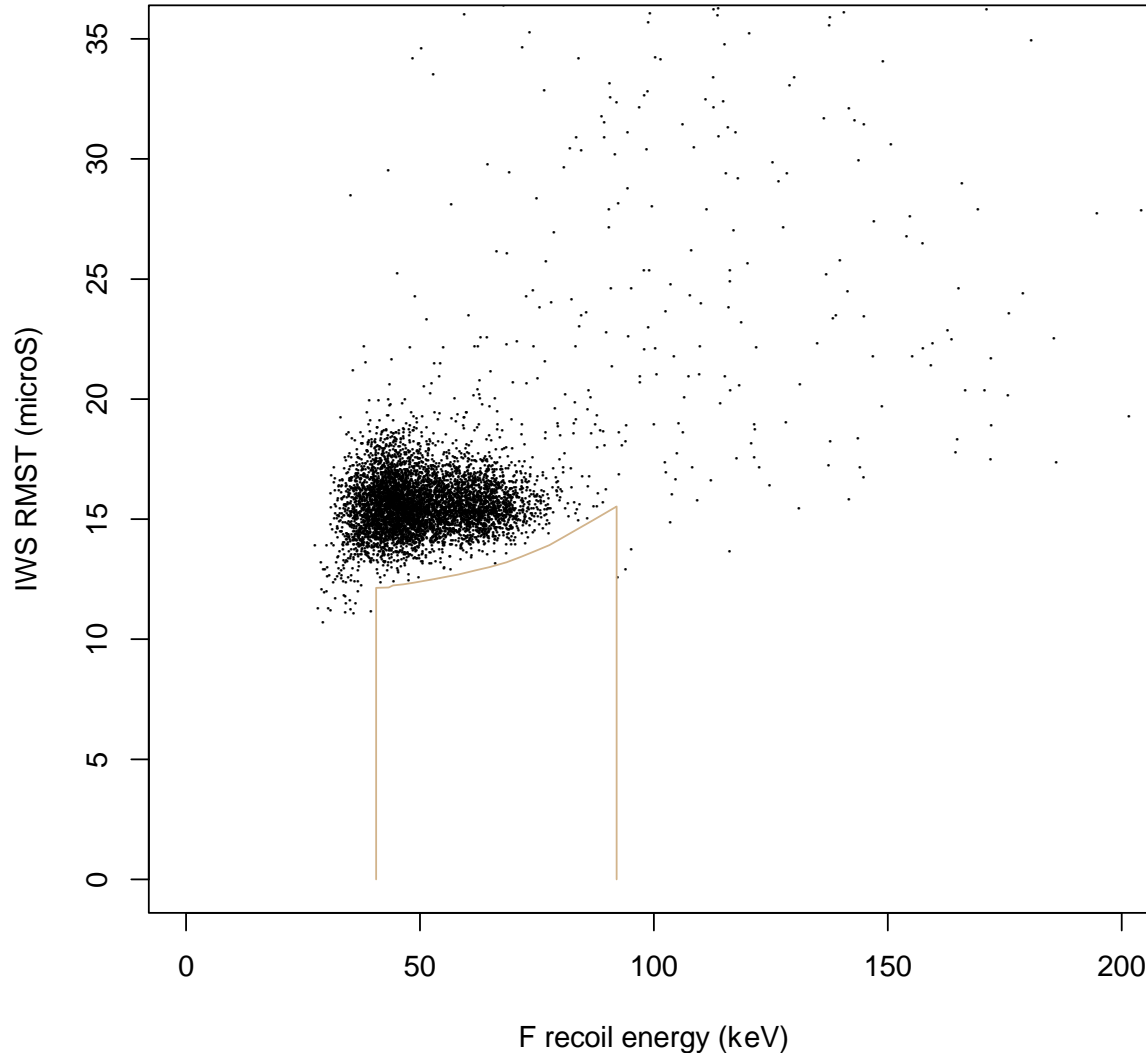

- Diffusion of the RPRs from the central cathode increases their width
- Use width as a crude discrimination parameter
- Black = Background
- Red = Neutron recoils

DRIFT-IId Data

CS2-CF4 Winter 09/10 Background Runs

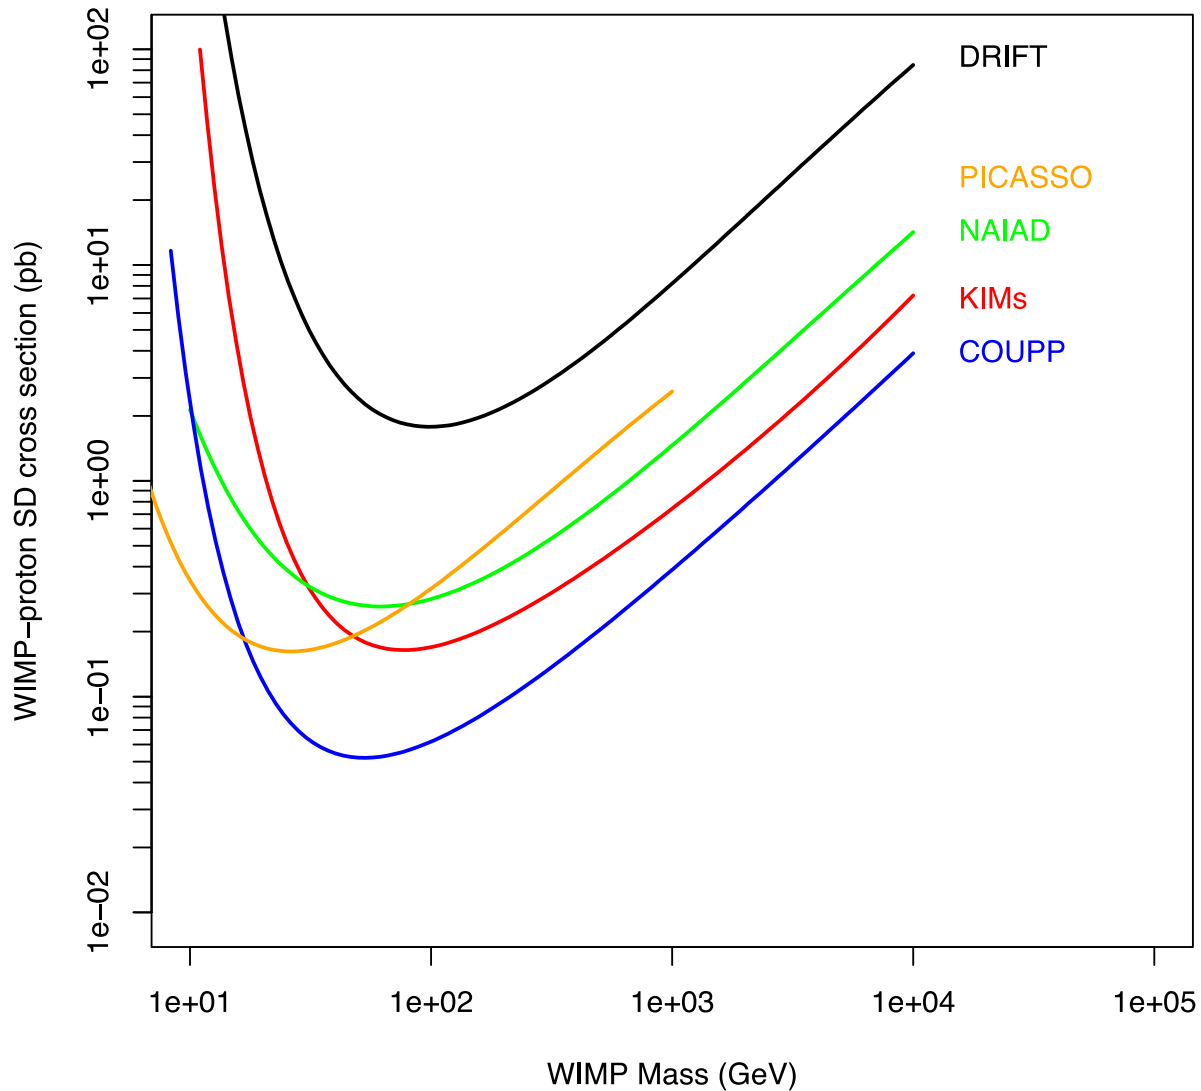

F Recoil Energies vs IWS RMST

47.4 days, 6152 events, 130 \pm 2 events per day

- Select a signal window
- Unfortunately for 100 GeV WIMPs the signal window => 8% efficiency of events passing the cuts

DRIFT-IIId Spin-Dependent WIMP Limits

Present Background Suppression

High energy alphas ➡ Suppression based on track length.

Neutrons ➡ Material with low U content. Good shielding.

Gammas ➡ Trigger with energy threshold above gammas.

Radon Progeny Recoils (RPR) ➡ Radon reduction. New thin film texturized cathode.

Low energy alphas ➡ New thin film texturized cathode.

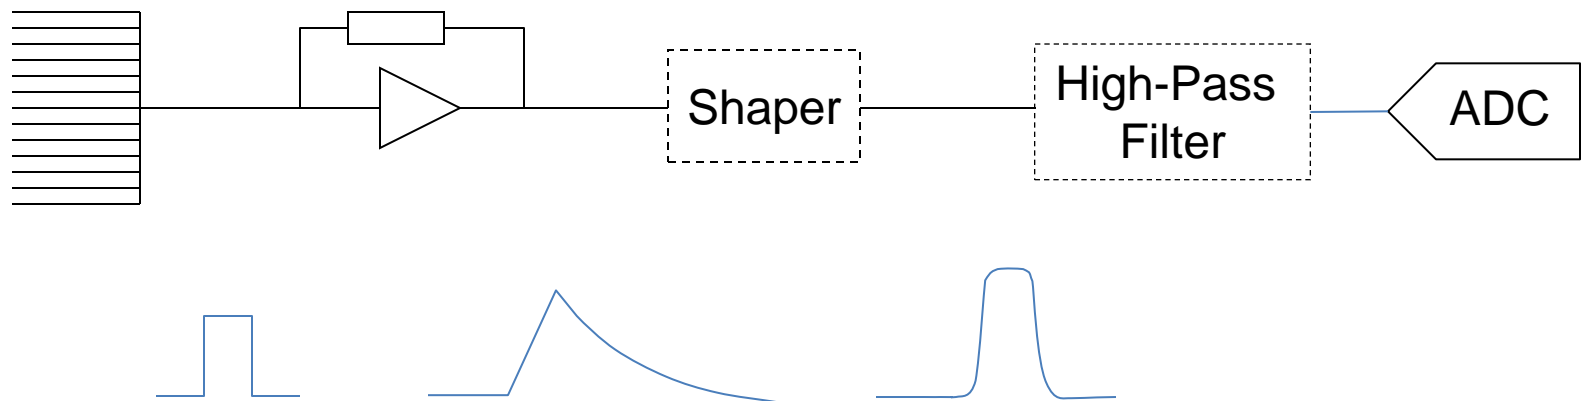

- All of our unsuppressed backgrounds are due to RPR's and low energy alphas originating from the cathode.
- Steps are taken to reduce Radon emission by systematically measuring every components.
- Thin film texturized cathode is about to be implemented.

Present Electronics on DRIFT-IIId

60-wire
grouping
20pF/wire

Preamp

4 x 8 channels

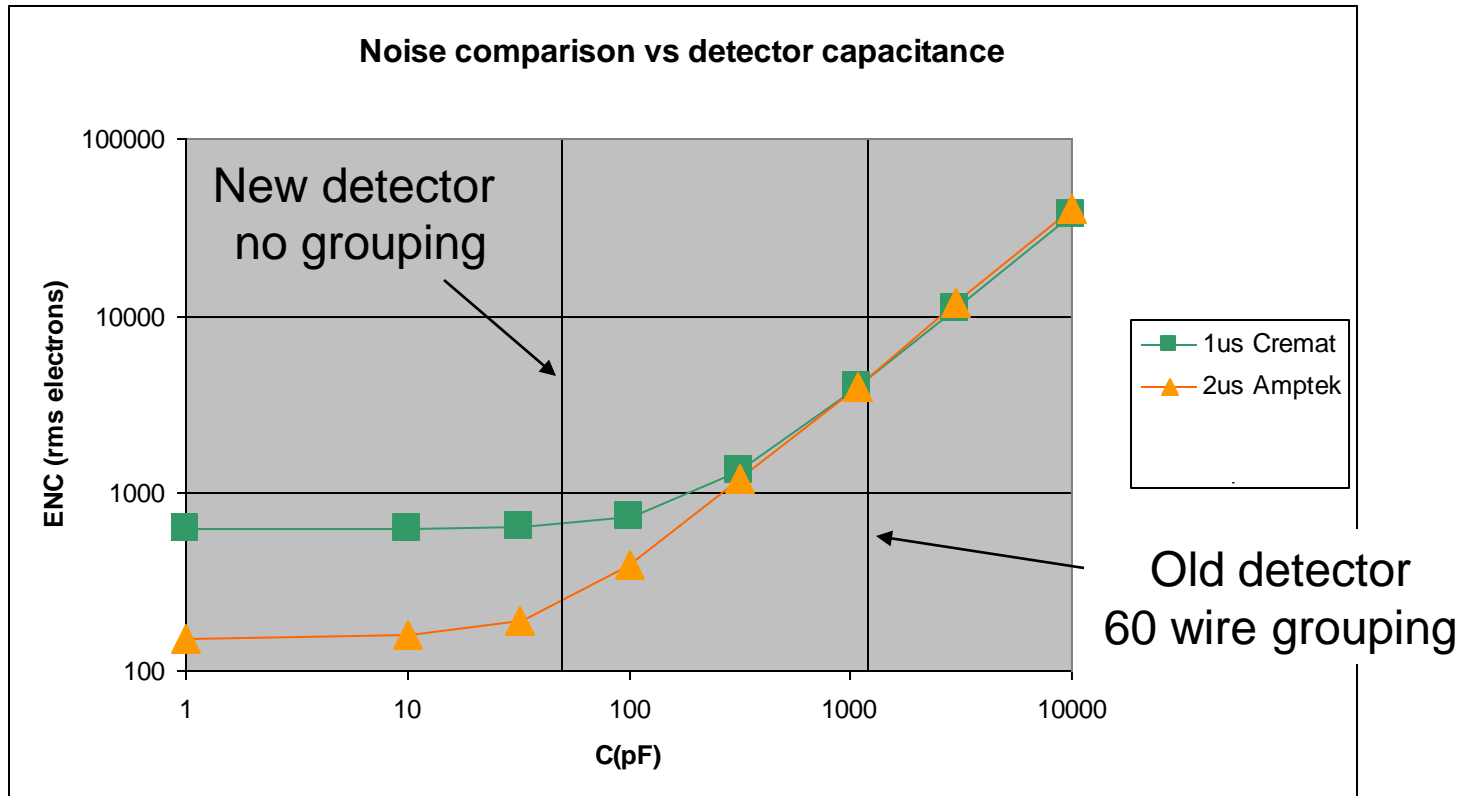

Shaping time = $4\mu\text{s}$

$C_{\text{det}} = 20\text{pF} \times 60 = 1200\text{ pF}$

enc = 3500 e^- RMS

- Triggers if any channel exceeds threshold
- All 36 channels are saved.
- Typical event rate $\sim 1\text{Hz}$
- ACQ = 1MHz

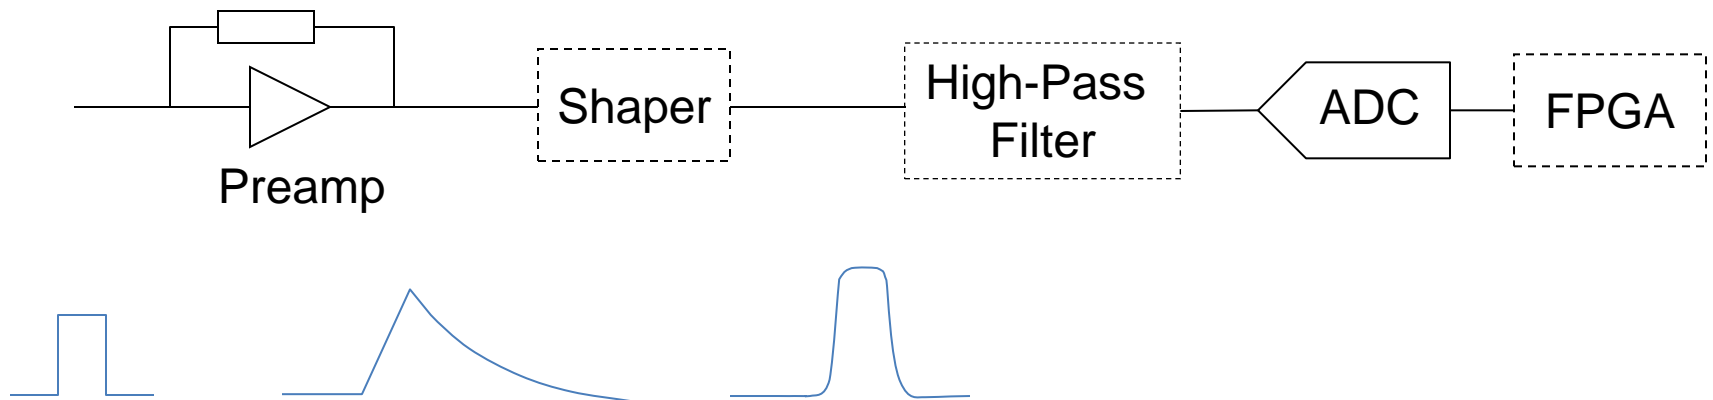

Preamp Thermal noise vs C_{det}

New Ideal Electronics on DRIFT-IIe

1 wire
50 pF

4 x 914 channels

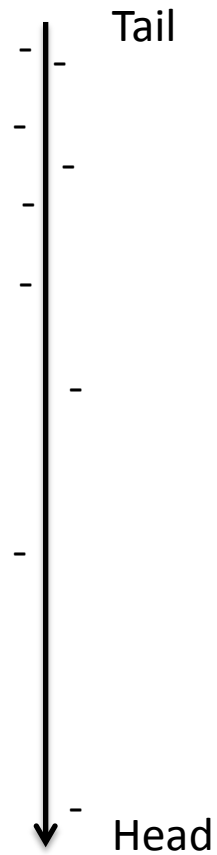

Shaping time = $1\mu\text{s}$
 $C_{\text{det}} = 50\text{pF}$
 $\text{enc} < 1000\text{ e}^- \text{ RMS}$

- Triggers if any channel exceeds threshold
- Only selected channels are saved.
- $\text{ACQ} \geq 1\text{MHz}$
- ~ 1800 channels

Benefits of new low-noise electronics on DRIFT-IIe

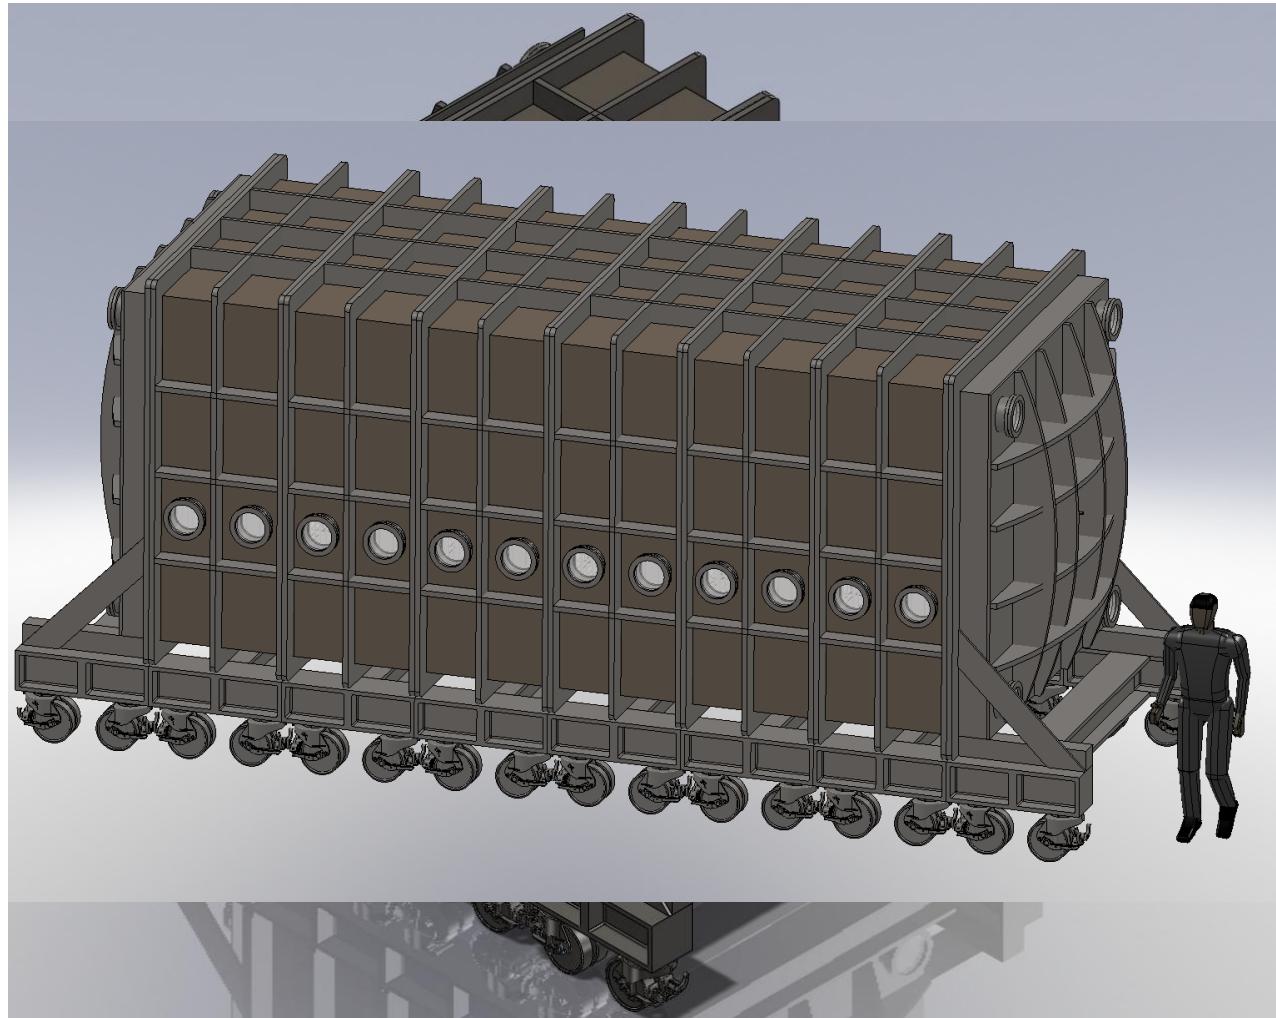

- Signal/noise increased by a factor 2 or 3. (Taking into account C_{det} and gas gain.)
 - Increased efficiency to detect WIMPS
 - Gamma detection and suppression.
 - Better head-tail identification.
 - Improved track direction measurement
 - Operation at lower gain with more CF_4 content
- Every wire is monitored. No grouping.
 - Edge veto in x.
 - Veto of Radon progeny plated on cathode without losing excessive fiducial volume.
 - Defective channels can be ignored; less down-time in repairs.
 - Proof of concept that every wire monitoring will be possible on DRIFT-III

Head – Tail detection

DRIFT-III

- Readout planes 4x bigger than DRIFT-II
- Same drift distance
- DRIFT-IIIa would have 10x the volume of a DRIFT-II class detector.
- Modular

Conclusion

- DRIFT-IId is now operating in Boulby.
- Negative ion drift to limit diffusion using CS₂
- 30-10 Torr of CS₂-CF₄ to optimize for spin-dependent limits, 139 g target mass.
- Upgrade to DRIFT-IIe is underway.
- New MWPC design
- New, clean, texturized thin film cathode.
- Exploring possibilities of single wire readout electronics.
- DRIFT-IIe is a relatively cheap, clean, stable and scalable technology.
